Abstract

This research is mainly concerned with studying the performance of the peristaltic flow of magnetohydrodynamic (MHD) viscous compressible flow under the impact of slip conditions, magnetic flux density, elastic features of the wave, and the liquid compressibility. The model taken represents a two-dimensional flexible sinusoidal rectangular duct with spring-damper backing. The perturbation approach is expanded as a series over the governing equations and the non-linear solution is introduced. Analytical relations describing the mean axial velocity, the mean velocity perturbation function, the net volumetric flow rate, the velocity corresponding to the elastic walls, and the critical wall tension are obtained with a small perturbation parameter known as amplitude ratio. The reversal flow occurs near the core of the channel when the critical tension is reached. The compliant wall features, magnetic flux density and slip conditions are strongly changing the dynamic behavior of the induced flow. The increase in magnetic flux causes a resisting effect to the flow and reducing the mean axial streamwise velocity and also for higher values of magnetic flux, the reverse flow occurs at the channel core. The damping property of the wall causes a reduction in the main flow but both of circumferential wall tension and the wall stiffness properties are enhancing the main flow rate. The flow of biofluids under external magnetic field through the human body is a good application related to this study such as the magnetic resonance imaging (MRI) and radiosurgery applications.

Keyword: Peristaltic flow; Wall properties; Compressible flow; MHD; Slip conditions

1. Introduction

The peristaltic pumping has a wide range of applications in biological and biomedical systems. Recently, the research in this area is developing rapidly and continuously due to its great importance. To be more specified, these researches are very helpful for physiologists to understand and predict what is happening for the human organs that move peristaltically under the various effects of physical properties, for instance, the magnetic flux density, the slip conditions, hall current, heat transfer, nanoparticles concentration, and the elastic muscles characteristics. To extend the view, the peristalsis occurs due to the alternation relaxation and contraction of the walls to force the content to move from one place to another. There are many real applications associated with the study of the collapsible elastic tubes. In biological systems, the peristalsis appears inside the human body in many organs as a result of collapsing compliant walls such as the internal blood hemodynamics through the cardiovascular system especially in veins above the heart, capillaries, and arteries under a cuff. The flexibility of the arteries in the real biological systems involves the muscle effect which changes the behavior of the blood flow. Experimentally, these models can be approached to reality by considering the tube law. The tube law consists of rubber tubes with finite length in the presence of self-induced vibratory oscillations. There are also many biofluids move peristaltically such as urine flow through the ureter, bolus locomotion in the digestive system, chyme transport in large and small intestines and lymph movement in the

lymphatic tract. Peristaltic principles are used in biomedical engineering to produce a heart-lung pump which helps to pump the blood through the body and lungs during open-heart surgery. On the other hand, in petroleum engineering, the mechanical peristaltic pump is used to extract the crude oil from the porous rock.

The peristaltic pumping is handled in many articles since Latham [1] who did the first attempt to analyze the nature of fluid motion using the principles of the peristaltic. Many articles [2-14] were concentrated on studying the impact of various physical properties on the peristaltic action of incompressible liquids. The slip flow occurs when the particles don't stick with the wall and there is a relative velocity at the boundaries, but the no-slip conditions appear when the particles of fluid adhere to the walls, and so the fluid velocity is zero relative to the wall. The effect of slip and no-slip conditions was taken into consideration in the studies of [7, 15, 16].

The magnetohydrodynamics (MHD) phenomena result from the mutual effect of a magnetic field and a conducting fluid flowing across it. Sud et al. [14] analyzed the influence of magnetic flux on the increase of the blood velocity. Akbar [17] studied the action of the transverse magnetic field on the peristaltic flow of nano-Eyring-Powell fluid. Hayat et al. [18] used the long-wavelength technique to study the influence of electromagnetic force resulting from the axial magnetic field on the pressure gradient and stream function of the peristaltic flow. Abbasi et al. [19] showed the impact of the variable viscosity and

the magnetic flux about the origin on the net flux and net axial velocity.

For the compressible flow point of view, Mekheimer et al. [20] study was concerned with the combined effects of magnetic intensity, the permeability of porous medium and the slip conditions on a compliant peristaltic wave of a driven Maxwellian fluid through a microchannel. Recent articles [15, 21-26] involve the peristaltic flow of MHD under various physical parameters such as nanoparticle concentration, Hall current intensity, the permeability of porous medium and wall slip coefficient are presented. The effectiveness of liquid compressibility within the peristaltic pumping was explained under an ultrasonic system by Aarts and Ooms [27]. It was found that the varying compressibility factor results in changing the fluid flow dynamic behavior. Eldesoky and Mousa [28, 29] introduced the combined influences of the liquid compressibility, relaxation time, porosity of porous medium and slip conditions on the net flux and the reversal flow through tapered pore. Whereas, Eldesoky et al. [30] were interested in knowing the nature of flow when suspended particles exist within the driven peristaltic two-phase flow under the perturbation approach. This idea is very useful to approach the real application system as it occurs in the case of blood clots and kidney stones move through the ureter. They found that the increase in particulate concentration results in a decrease in the main flow and an increase in the reversed pressure and reversal flow. Abumandour et al. [31] in their recent study did a complementary study to Eldesoky et al. [30] as they added the slip conditions at the boundaries through the two-phase flow.

Compliance is the ability of the conduit walls to expand and accommodate the increased content. The walls of biological organs are elastic and extensible. The force corresponding to walls appears as a result of interaction between the muscle forces, internal flow, and external wall forces. Choosing the compliant walls is very important to indicate its effectiveness in the flow behavior in the critical collapsible organs in the human body. The flexible walls features are wall stiffness, damping, tension, and wall bending factor. Pandey and Chaube [32] studied the interaction of wall flexibility with the peristaltic locomotion of couple stress fluid. Javed et al. [33] introduced the effect of the compliant walls on the flow of non-Newtonian fluid. Elnaby and Haroun [34] expressed the wall elasticity by using a new compliant model and showed that net flux and mean velocity have been changed at different values of wall tension, and damping. Eldesoky et al. [35] were mainly interested in showing the different effects of wall flexibility, slip conditions, liquid compressibility and relaxation time on the peristalsis of Maxwellian compressible flow. The results showed that all the important physical properties have participated in changing the characteristics of the flowing flow. Whereas, Eldesoky et al. [36] added the effect of heat transfer which is very helpful in the case of cancer disease treatment and showed that the wall elasticity and wall slip made a mutation in the net flow behavior. Mekheimer and Abdel-Wahab [37] investigated the combined effects of slip

compliant boundaries of a microchannel and liquid compressibility on the physical fluid properties of the induced surface acoustic wave. Recently, there is a great concentration on this point of study. In Sadaf and Abdelsalam [38] the performance of the injected nanoparticles is investigated in a mixed flexible peristaltic blood model using average lubrication methodology. It was found that hybrid nanoparticles were affecting the heat transfer rate rather than the set nanoparticles. Bhatti et al. [39] have investigated the Sutterby fluid model to understand the mechanism of the blood hemodynamics under the effect of nanomaterials characteristics on the runoff of the gyrotactic microorganisms through the blood in a narrow artery. The accurate perturbation technique up to the third order was performed on the model's governing equations. And the results showed that non-Newtonian property has a resisting impact and the temperature distribution was high while transition from convergent position to divergent one through the artery. Abdelsalam and Bhatti [40] have analyzed also the peristaltic locomotion of non-Newtonian nanofluid convective flow in the presence of heat transfer and carrying some oxytotic microorganisms using the homotopy perturbation methodology (HPM). Elmaboud et al. [41] have entered the electromagnetic force field and the heat flux on the wavy flow of two layer immiscible flow. The analytical methodology is the homotopy analysis method (HAM). The results showed that the electric field boosts the net flow whereas the magnetic force did not. Abdelsalam and Mekheimer [42] have investigated the case of rotating channel with constant angular velocity and carrying couple stress fluid moving peristaltically under the exact solution of (HPM). Eldesoky et al. [43] have combined the mutual effects of thermal heating and magnetic flux in the presence of small circular suspensions through the blood flow in a catheter tube under the approximation of the long wave technique. The results showed that the heat was enhancing the net axial velocity while the suspension concentration caused a reduction in the flow rate. While Eldesoky et al. [44] added the porosity effect to the Magnetohydrodynamics (MHD), heating, and dusty suspensions properties on the peristaltic flow of the blood via a two dimensional channel under the assumptions of perturbation scheme. The more dust led to more decrease in the fluid temperature and also the magnetic force has changed the fluid temperature depending on the time and position. Many recent articles [45-49] were interested in the peristaltic mechanism under the different effects of heat and mass transfer, magnetic flux, suspensions, nanoparticles concentration, entropy generation and the behavior of the tumor cells under the magnetism in the presence of the peristalsis for both compressible and incompressible flow and different flow models such as Maxwellian, Bingham models using various analytical and numerical methods.

From the comprehensive survey, it is noted that no previous attempt has combined the influences of magnetic flux density, compliant wall features, wall slip conditions and liquid compressibility on the compressible peristaltic transport through a two-dimensional channel. Therefore,

the authors are interested in this study because of its importance in the biomedical field. It is can be found in the real-life applications such as the radiosurgery and magnetic resonance radiation on the human body. The problem model is considered to be a sinusoidal elastic wall with spring-damper backing. The perturbation methodology with a small perturbation parameter called amplitude ratio is introduced. The flow is considered to be a free pumping case by neglecting the pressure gradient in the beginning. The chosen model approaches the real systems in case of exposing the human body to magnetic field radiation. And the current study is a special case related with that of Mekheimer et al [37] if the magnetic effect is neglected.

2. The problem formulation

Problem Geometry

The undertaken model is supposed to be a two-dimensional elastic sinusoidal channel with spring-damper backing in the presence of the induced transverse magnetic field, See Fig. 1.

Figure 1- The peristaltic geometry with spring-damper backing

Mathematical Formulation

Governing equations

The basic system of equations (mass and momentum conservation) and equation of state for compressible flow in presence of magnetic field are expressed as [20, 27]:

Continuity equation

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \vec{V}) = 0 \tag{1}$$

Momentum equation

$$\rho \frac{\partial \vec{V}}{\partial t} + \rho (\vec{V} \cdot \nabla) \vec{V} = -\nabla \bar{p} + \mu (\nabla^2 \vec{V}) + \frac{\mu}{3} \nabla (\nabla \cdot \vec{V}) - \vec{F} \tag{2}$$

Equation of state

$$\frac{\partial \rho}{\partial p} = \rho k^* \tag{3}$$

$$\rho = \rho_o e^{k^*(p-p_c)} \tag{4}$$

The compliant wall geometry is given by:

$$\eta(x, t) = a \cos \frac{2\pi}{\lambda} (x - ct) \tag{5}$$

It is defined at the upper and lower wall as follows:

$$y = \pm (d + \eta) = \pm \left(d + a \cos \frac{2\pi}{\lambda} (x - ct) \right) \tag{6}$$

The elastic wall equation is expressed as [37]:

$$L(\eta) = p - p_o = -T \frac{\partial^2 \eta}{\partial x^2} + m \frac{\partial^2 \eta}{\partial t^2} + D \frac{\partial \eta}{\partial t} + B \frac{\partial^4 \eta}{\partial x^4} + K \eta \tag{7}$$

The electromagnetic force and the velocity vector are expressed by:

$$\vec{F} = \sigma u B_o^2 \hat{i} \tag{8}$$

$$\vec{V} = u \hat{i} + v \hat{j} \tag{9}$$

Boundary conditions

The walls of the channel are controlling the shape and the dynamical properties of the flow. The main characteristics corresponding to the boundaries $y = \pm (d + \eta)$ are the parameter of interest as follows:

Wall slip:

$$u = \mp A \frac{\partial u}{\partial y} \tag{10}$$

Wall impermeability:

$$v = \pm \frac{\partial \eta}{\partial t} \tag{11}$$

The surface wall interaction forces are:

$$\frac{\partial L}{\partial x} = \frac{\partial P}{\partial x} = -\rho \left(\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial x} \right) + \mu \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) + \frac{\mu}{3} \frac{\partial}{\partial x} \left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) - \sigma u B_o^2 \tag{12}$$

Solution methodology

Firstly, non-dimensional analysis is done for both governing equations and boundary conditions. Secondly, the perturbation series is expanded over the resulting dimensionless governing equations and the boundary conditions. Finally, the non-linear approximation is presented for the resulting relations. Taylor series expansions are used to simplify the boundary conditions.

Non-dimensional analysis

Dimensionless flow parameters are:

$$\bar{x} = \frac{x}{d}, \quad \bar{y} = \frac{y}{d}, \quad \bar{u} = \frac{u}{c}, \quad \bar{v} = \frac{v}{c}, \quad \bar{\eta} = \frac{\eta}{d}, \quad \bar{t} = \frac{ct}{d}, \quad \bar{p} = \frac{P}{\rho_0 c^2}, \quad \bar{p}_c = \frac{P_c}{\rho_0 c^2} \quad (13)$$

Dimensionless elastic wall parameters are:

$$\bar{D} = \frac{Dd}{\rho_0 v}, \quad \bar{B} = \frac{B}{\rho_0 d v^2}, \quad \bar{K} = \frac{K d^3}{\rho_0 v^2}, \quad \bar{m} = \frac{m}{\rho_0 d}, \quad \bar{T} = \frac{T d}{\rho_0 v^2} \quad (14)$$

Dimensionless system of equations are:

$$\frac{\partial \rho}{\partial t} + u \frac{\partial \rho}{\partial x} + v \frac{\partial \rho}{\partial y} + \rho \left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) = 0 \quad (15)$$

$$\rho \left[\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right] = - \frac{\partial p}{\partial x} + \frac{1}{R} \left[\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right] + \frac{1}{3R} \frac{\partial}{\partial x} \left[\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right] + - \frac{H_a^2}{R} u \quad (16)$$

$$\rho \left[\frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} \right] = - \frac{\partial p}{\partial y} + \frac{1}{R} \left[\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} \right] + \frac{1}{3R} \frac{\partial}{\partial y} \left[\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right] \quad (17)$$

$$\rho = e^{\chi(p-p_0)} \quad (18)$$

Dimensionless boundary conditions at $y = \pm(1 + \eta)$ with $\eta = \varepsilon \alpha \cos(x - t)$ are

$$\left. \begin{aligned} u &= \mp Kn \frac{\partial u}{\partial y} \\ v &= \pm \varepsilon \alpha \sin \alpha (x - t) \end{aligned} \right\} \quad (19)$$

$$\begin{aligned} \frac{\partial}{\partial x} \left(m \frac{\partial^2}{\partial t^2} + \frac{D}{R} \frac{\partial}{\partial t} + \frac{B}{R^2} \frac{\partial^4}{\partial x^4} - \frac{T}{R^2} \frac{\partial^2}{\partial x^2} + \frac{K}{R^2} \right) \eta &= - \rho \left(\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) + \frac{1}{R} \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) \\ &+ \frac{1}{3R} \frac{\partial}{\partial x} \left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) - \frac{H_a^2}{R} u \end{aligned} \quad (20)$$

Perturbation series

Expanding the properties of the fluid as perturbation series with small amplitude ratio (ε) as following

$$\left. \begin{aligned} p &= p_0 + \varepsilon p_1(x, y, t) + \varepsilon^2 p_2(x, y, t) + \dots \\ u &= \varepsilon u_1(x, y, t) + \varepsilon^2 u_2(x, y, t) + \dots \\ v &= \varepsilon v_1(x, y, t) + \varepsilon^2 v_2(x, y, t) + \dots \\ \rho &= 1 + \varepsilon \rho_1(x, y, t) + \varepsilon^2 \rho_2(x, y, t) + \dots \end{aligned} \right\} \quad (21)$$

Free pumping case means (u_0 and $v_0 = 0$).

Two systems of equations are obtained in terms of ε and ε^2 as a result of substituting Eq. 21 into Eqs. (15-18).

The system of ε is

$$\frac{\partial u_1}{\partial t} + \frac{\partial u_1}{\partial x} + \frac{\partial v_1}{\partial y} = 0 \quad (22)$$

$$\frac{\partial u_1}{\partial t} = - \frac{\partial p_1}{\partial x} + \frac{1}{R} \left(\frac{\partial^2 u_{f1}}{\partial x^2} + \frac{\partial^2 u_{f1}}{\partial y^2} \right) + \frac{1}{3R} \frac{\partial}{\partial x} \left(\frac{\partial u_1}{\partial x} + \frac{\partial v_1}{\partial y} \right) - \frac{H_a^2}{R} u_1 \quad (23)$$

$$\frac{\partial v_1}{\partial t} = - \frac{\partial p_1}{\partial y} + \frac{1}{R} \left(\frac{\partial^2 v_1}{\partial x^2} + \frac{\partial^2 v_1}{\partial y^2} \right) + \frac{1}{3R} \frac{\partial}{\partial y} \left(\frac{\partial u_1}{\partial x} + \frac{\partial v_1}{\partial y} \right) \quad (24)$$

$$\rho_1 = \chi p_1 \quad (25)$$

The system of ε^2 is

$$\frac{\partial u_2}{\partial t} + u_1 \frac{\partial \rho_1}{\partial x} + v_1 \frac{\partial \rho_1}{\partial y} + \frac{\partial u_2}{\partial x} + \frac{\partial v_2}{\partial y} + \rho_1 \left(\frac{\partial u_1}{\partial x} + \frac{\partial v_1}{\partial y} \right) = 0 \quad (26)$$

$$\left[\frac{\partial u_2}{\partial t} + u_1 \frac{\partial u_1}{\partial x} + v_1 \frac{\partial u_1}{\partial y} + \rho_1 \frac{\partial u_1}{\partial t} \right] = - \frac{\partial p_2}{\partial x} + \frac{1}{R} \left(\frac{\partial^2 u_2}{\partial x^2} + \frac{\partial^2 u_2}{\partial y^2} \right) + \frac{1}{3R} \frac{\partial}{\partial x} \left(\frac{\partial u_2}{\partial x} + \frac{\partial v_2}{\partial y} \right) - \frac{H_a^2}{R} u_2 \quad (27)$$

$$\left[\frac{\partial v_{f2}}{\partial t} + u_1 \frac{\partial v_1}{\partial x} + v_1 \frac{\partial v_1}{\partial y} + \rho_1 \frac{\partial v_1}{\partial t} \right] = - \frac{\partial p_2}{\partial y} + \frac{1}{R} \left(\frac{\partial^2 v_2}{\partial x^2} + \frac{\partial^2 v_2}{\partial y^2} \right) + \frac{1}{3R} \frac{\partial}{\partial y} \left(\frac{\partial u_2}{\partial x} + \frac{\partial v_2}{\partial y} \right) \quad (28)$$

$$\rho_2 = \chi p_2 + \frac{\chi^2 p_1^2}{2} \quad (29)$$

Taylor series expansion about $y = \pm 1$ is given by

$$\left. \begin{aligned} u(\pm\eta) &= u(\pm 1) \pm \eta(x, t) \frac{\partial u(\pm 1)}{\partial y} + \frac{\eta^2(x, t)}{2!} \frac{\partial^2 u(\pm 1)}{\partial y^2} + \dots \\ v(\pm\eta) &= v(\pm 1) \pm \eta(x, t) \frac{\partial v(\pm 1)}{\partial y} + \frac{\eta^2(x, t)}{2!} \frac{\partial^2 v(\pm 1)}{\partial y^2} + \dots \end{aligned} \right\} \quad (30)$$

Substituting perturbation series (21) and Taylor expansions (30) into the boundary conditions (19) and (20) two sets of equations are obtained. The ϵ set is

$$u_1(\pm 1) = \mp Kn \frac{\partial u_1(\pm 1)}{\partial y} \quad (31)$$

$$v_1(\pm 1) = \mp \frac{i\alpha}{2} \left(e^{i\alpha(x-t)} - e^{-i\alpha(x-t)} \right) \quad (32)$$

$$\begin{aligned} & -R \frac{\partial u_1(\pm 1)}{\partial t} + \frac{1}{R} \left(\frac{\partial^2 u_1(\pm 1)}{\partial x^2} + \frac{\partial^2 u_1(\pm 1)}{\partial y^2} \right) + \frac{1}{3R} \frac{\partial}{\partial x} \left(\frac{\partial u_1(\pm 1)}{\partial x} + \frac{\partial v_1(\pm 1)}{\partial y} \right) - H_a^2 u_1(\pm 1) \\ & = \left[-\frac{i\delta_a}{2} \left(e^{i\alpha(x-t)} - e^{-i\alpha(x-t)} \right) + \frac{\delta_b}{2} \left(e^{i\alpha(x-t)} + e^{-i\alpha(x-t)} \right) \right] \end{aligned} \quad (33)$$

The ϵ^2 set is

$$u_2(\pm 1) \pm \frac{1}{2} \left(e^{i\alpha(x-t)} + e^{-i\alpha(x-t)} \right) \frac{\partial u_1(\pm 1)}{\partial y} = \mp Kn \frac{\partial u_2(\pm 1)}{\partial y} - \frac{Kn}{2} \left(e^{i\alpha(x-t)} + e^{-i\alpha(x-t)} \right) \frac{\partial^2 u_1(\pm 1)}{\partial y^2} \quad (34)$$

$$v_2(\pm 1) \pm \frac{1}{2} \left(e^{i\alpha(x-t)} + e^{-i\alpha(x-t)} \right) \frac{\partial v_1(\pm 1)}{\partial y} = 0 \quad (35)$$

The Nonlinear solution

Using the non-linear expressions of [27] to simplify the solution as follows:

$$u_1(x, y, t) = U_1(y) e^{i\alpha(x-t)} + \bar{U}_1(y) e^{-i\alpha(x-t)} \quad (36a)$$

$$v_1(x, y, t) = V_1(y) e^{i\alpha(x-t)} + \bar{V}_1(y) e^{-i\alpha(x-t)} \quad (36b)$$

$$p_1(x, y, t) = P_1(y) e^{i\alpha(x-t)} + \bar{P}_1(y) e^{-i\alpha(x-t)} \quad (36c)$$

$$\rho_1(x, y, t) = \chi P_1(y) e^{i\alpha(x-t)} + \chi \bar{P}_1(y) e^{-i\alpha(x-t)} \quad (36d)$$

The second order non-linear approach is given by

$$u_2(x, y, t) = U_{20}(y) + U_2(y) e^{2i\alpha(x-t)} + \bar{U}_2(y) e^{-2i\alpha(x-t)} \quad (37a)$$

$$v_2(x, y, t) = V_{20}(y) + V_2(y) e^{2i\alpha(x-t)} + \bar{V}_2(y) e^{-2i\alpha(x-t)} \quad (37b)$$

$$p_2(x, y, t) = P_{20}(y) + P_2(y) e^{2i\alpha(x-t)} + \bar{P}_2(y) e^{-2i\alpha(x-t)} \quad (37c)$$

$$\rho_2(x, y, t) = D_{20}(y) + D_2(y) e^{2i\alpha(x-t)} + \bar{D}_2(y) e^{-2i\alpha(x-t)} \quad (37d)$$

Applying the nonlinear approach (36) and (37) in relations. (22-29) and their boundary conditions (31 -35) resulting in the following two sets of differential equations. The first-order set is

$$V_1' + i\alpha U_1 = i\alpha\chi P_1 \quad (38)$$

$$-i\alpha R U_1 = -i\alpha R P_1 + U_1'' - \alpha^2 U_1 + \frac{1}{3} i\alpha [V_1' + i\alpha U_1] - H_a^2 U_1 \quad (39)$$

$$-i\alpha R U_1 - i\alpha R V_1 = -R P_1' + V_1'' - \alpha^2 V_1 + \frac{1}{3} \frac{d}{dy} [V_1' + i\alpha U_1] \quad (40)$$

Under the following boundary conditions

$$U_1(\pm 1) = \mp Kn \frac{\partial U_1(\pm 1)}{\partial y} \tag{41}$$

$$V_1(\pm 1) = \mp \frac{i\alpha}{2} \tag{42}$$

$$\frac{\partial^2 U_1(\pm 1)}{\partial y^2} - \left[\frac{4}{3}\alpha^2 - i\alpha R + H_a^2 \right] U_1(\pm 1) + \frac{i\alpha}{3} \frac{\partial V_1(\pm 1)}{\partial y} = R \delta \tag{43}$$

Following the same steps of the methodology used in [37] results in the equations of velocity and pressure as follows:

$$U_1(y) = R_6 C_1 \cosh(L_1 y) + R_7 C_2 \cosh(L_2 y) \tag{44}$$

$$V_1(y) = C_1 \sinh(L_1 y) + C_2 \sinh(L_2 y) \tag{45}$$

$$P_1(y) = R_4 C_1 \cosh(L_1 y) + R_5 C_2 \cosh(L_2 y) \tag{46}$$

The second-order set is

$$V_{20}' = -\chi \left[P_1 \bar{V}_1' + \bar{P}_1 V_1' + V_1 \bar{P}_1' + \bar{V}_1 P_1' \right] \tag{47}$$

$$U_{20}'' = R \left[i\alpha\chi P_1 \bar{U}_1 - i\alpha\chi \bar{P}_1 U_1 + V_1 \bar{U}_1' + \bar{V}_1 U_1' \right] + H_a^2 U_{20} \tag{48}$$

$$-R P_{20}' + \frac{4}{3} V_{20}'' = R \left[i\alpha\chi P_1 \bar{V}_1 - i\alpha\chi \bar{P}_1 V_1 - i\alpha U_1 \bar{V}_1 + i\alpha \bar{U}_1 V_1 + V_1 \bar{V}_1' + \bar{V}_1 V_1' \right] \tag{49}$$

Under the following boundary conditions

$$U_{20}(\pm 1) \pm \frac{1}{2} \left(\bar{U}_1'(\pm 1) + U_1'(\pm 1) \right) = \mp Kn \left[U_{20}'(\pm 1) \pm \frac{1}{2} \left(\bar{U}_1''(\pm 1) + U_1''(\pm 1) \right) \right] \tag{50}$$

$$V_{20}(\pm 1) \pm \frac{1}{2} \left[V_1'(\pm 1) + \bar{V}_1'(\pm 1) \right] = 0 \tag{51}$$

The solution of the second-order equations (46–48) under their corresponding boundary conditions (49) and (50) is given by

$$U_{20}(y) = R E(y) + D_2 \text{Cosh} \sqrt{\delta_c} y + D_3 \text{Sinh} \sqrt{\delta_c} y \tag{52}$$

$$V_{20}(y) = -\chi \left[P_1(y) \bar{V}_1(y) + \bar{P}_1(y) V_1(y) \right] \tag{53}$$

$$E(y) = \left[\frac{\delta_1}{2} \left(\frac{\cosh(L_1 + \bar{L}_1)y}{(L_1 + \bar{L}_1)^2 - \delta_c} + \frac{\cosh(L_1 - \bar{L}_1)y}{(L_1 - \bar{L}_1)^2 - \delta_c} \right) + \frac{\delta_2}{2} \left(\frac{\cosh(L_1 + \bar{L}_2)y}{(L_1 + \bar{L}_2)^2 - \delta_c} + \frac{\cosh(L_1 - \bar{L}_2)y}{(L_1 - \bar{L}_2)^2 - \delta_c} \right) \right. \\ \left. + \frac{\delta_3}{2} \left(\frac{\cosh(L_2 + \bar{L}_1)y}{(L_2 + \bar{L}_1)^2 - \delta_c} + \frac{\cosh(L_2 - \bar{L}_1)y}{(L_2 - \bar{L}_1)^2 - \delta_c} \right) + \frac{\delta_4}{2} \left(\frac{\cosh(L_2 + \bar{L}_2)y}{(L_2 + \bar{L}_2)^2 - \delta_c} + \frac{\cosh(L_2 - \bar{L}_2)y}{(L_2 - \bar{L}_2)^2 - \delta_c} \right) \right. \\ \left. + \frac{\delta_5}{2} \left(\frac{\cosh(L_1 + \bar{L}_1)y}{(L_1 + \bar{L}_1)^2 - \delta_c} - \frac{\cosh(L_1 - \bar{L}_1)y}{(L_1 - \bar{L}_1)^2 - \delta_c} \right) + \frac{\delta_6}{2} \left(\frac{\cosh(L_2 + \bar{L}_1)y}{(L_2 + \bar{L}_1)^2 - \delta_c} - \frac{\cosh(L_2 - \bar{L}_1)y}{(L_2 - \bar{L}_1)^2 - \delta_c} \right) \right. \\ \left. + \frac{\delta_7}{2} \left(\frac{\cosh(L_1 + \bar{L}_2)y}{(L_1 + \bar{L}_2)^2 - \delta_c} - \frac{\cosh(L_1 - \bar{L}_2)y}{(L_1 - \bar{L}_2)^2 - \delta_c} \right) + \frac{\delta_8}{2} \left(\frac{\cosh(L_2 + \bar{L}_2)y}{(L_2 + \bar{L}_2)^2 - \delta_c} - \frac{\cosh(L_2 - \bar{L}_2)y}{(L_2 - \bar{L}_2)^2 - \delta_c} \right) \right] \tag{54}$$

The dynamic behavior of the flow is analyzed utilizing the net axial velocity, the net flow rate, the mean velocity perturbation function and the critical wall tension which is similar in effect to the pressure gradient at which reversal flow occurs. All these relations are obtained as follows:

$$\langle V_x(y) \rangle = \varepsilon^2 U_{20}(y) \tag{55}$$

$$G(y) = -\frac{200}{\alpha^2 R^2} (E(y) - E(1)) \tag{56}$$

$$\langle Q \rangle = \varepsilon^2 \int_0^1 U_{20}(y) dy \tag{57}$$

The critical values of wall tension occur corresponding to the reflux conditions when

$$\langle V_x(0) \rangle = 0 \tag{58}$$

3. Graphical Results and discussion

Verification of analytical method

Checking and validating the results of the work requires a comparative analysis with the previous studies and the results of Mekheimer et al [37] is achieved for the present study in the absence of magnetic flux effect $Ha = 0$. For instance, Figure 2- a, b, and c) (corresponding to Table (1)) are obtained when $Ha = 0$ which are exactly coincident with that of Mekheimer et al [37].

Results and discussion

The alternation of magnetic flux density, compliant walls characteristics and flow properties have obvious effectiveness in changing the dynamical behavior of the flowing flow. This is represented in the following section. Figure (3) (corresponding to Table (2)) shows the various effects of wall damping, wall stiffness, wall tension, wall slip, magnetic flux, and liquid compressibility on the net axial velocity. Figure 3(a) shows the resisting action of the wall damping on the motion. It is also noted that the wall tension, spring stiffness and slip at walls are enhancing the net flux as the resulting increase in mean axial velocity according to the increase in the spring stiffness (K), longitude wall tension (T) and Knudsen number (Kn), see Figures 3(b, c, and d). Figure 3(e) shows the reduction of the mean velocity due to the increase of magnetic flux density since the reversal flow begins to appear near the walls when the magnetic factor ($Ha = 4$) and the reverse effect increases near the boundaries at high values of magnetic flux. The liquid compressibility (χ) is inversely proportional to the net streamwise velocity so it causes the mean flow flux to decrease and this action is illustrated in Figure 3(f). The elastic compliant walls properties and wall slip are highly affecting the velocity distribution, especially at the boundaries, so that it is important to get close to the boundaries to analyze the dynamic nature of the flow and to determine the conditions at which the reversal flow will occur. The next section is related with the analysis of the velocity at the boundaries (D_{wall}) under the varying values of magnetic flux factor (Ha), the wall Knudsen number (Kn), the wall damping factor (D), the longitude wall tension (T) and the fluid compressibility (χ). All these effects are shown in Fig. (4) (corresponding to Table (3)). The analysis of the streamwise velocity at the elastic channel walls draws the interest to explain what exactly exists and happens to the behavior of the flow near the walls under the change in elastic wall features and magnetic flux intensity. It is shown in Figure 4(a) that the increase in bending coefficient (B) boosts the streamwise velocity at the channel walls (D_{wall}). The influence of wall tension (T) and stiffness (K) is illustrated in Figures 4(d, and f) and it is noted that (T) and (K) have a similar proportional effect of (B). The increase of slip Knudsen number (Kn) in Figure 4(c) enhances the streamwise velocity near the walls (D_{wall}) due to the slipping effect. Whereas, Figure 4(b) discloses that the rise of wall damping coefficient (D) resists the motion and causes a reduction in (D_{wall}). Figure 4(e) is clearly showing the

impact of Compressibility number (χ) on (D_{wall}) and the results indicate the inversely proportional relation between (χ) and (D_{wall}). The rise in the transverse magnetic flux (Ha) parameter reduces the mean streamwise velocity at walls due to its resistive action; see Figure 4(g). The considered ranges of the governing parameters are taken according to its typical and experimental values in the physical applications related to this case of study. The flow regimes were classified into continuum, slip, transition and free molecular according to Knudsen number ranges. If $Kn < 0.001$, the fluid is considered as a continuous medium as a result of neglecting the molecules mean free path compared to the geometrical dimensions. If $0.001 < Kn < 0.1$, then the fluid tends to slip corresponding to the domain walls. If $0.1 < Kn < 3.0$, so that it is the transition flow regimes. When $Kn > 3.0$, the fluid flow exists in the free molecular case. The range of compressibility number is $0 \leq \chi \leq 1$, when $\chi = 0$ the fluid is considered to be incompressible liquid and when $\chi = 1$ case of fully compressible flow exists. The elastic wall parameters ranges are selected according to [50, 51].

4. Conclusions

The principle goal of this study is concerned with the combined interaction of magnetic flux (Ha), the slip conditions (Kn), liquid compressibility (χ) and compliant elastic wall characteristics (D, T, K and B) on the mean axial streamwise velocity $\langle \frac{V_x}{\varepsilon^2} \rangle$ and the mean streamwise velocity corresponding to elastic channel walls (D_{wall}). The relation describing the flow behavior such as pressure gradient, mean axial streamwise velocity and the net flow flux is derived from the governing continuity and momentum equations by using the perturbation methodology with small perturbation amplitude ratio. The results disclose that the magnetic field flux is resisting the

flow motion and cause a reduction in the flow flux. The raise in magnetic flux results in a decrease in the mean axial streamwise velocity. For higher values of magnetic flux, the reverse flow is appearing at the core of the channel. And near the boundaries, a similar effect is obtained. The wall damping has also a drag effect on the flow motion and near the walls while the spring stiffness and wall tension are boosting the net flow rate and the mean axial velocity. The slipping at the walls also enhances the net streamwise velocity $\langle \frac{V_x}{\varepsilon^2} \rangle$ and (D_{wall}). on contrast the liquid compressibility (χ) has a strong action in reducing $\langle \frac{V_x}{\varepsilon^2} \rangle$ and (D_{wall}).

Nomenclature

$2d$	Channel mean width.	D	Damping parameter.
\vec{V}	The fluid velocity vector.	B	Wall bending coefficient.
p	The fluid pressure.	K	Spring stiffness.
ρ	The fluid density.	p_o	The out-surface pressure and considered to be zero.
x	The streamwise Cartesian direction.	A	Mean free path of molecules.
y	The normal Cartesian direction.	R	Reynolds number.
t	The time.	χ	The compressibility number.
u	The fluid velocity in the x -direction.	α	The wave number.
v	The fluid velocity in the y -direction.	ε	The amplitude ratio.
μ	The fluid dynamic viscosity.	Kn	Knudsen number.
K^*	The liquid compressibility factor.	ν_o	Kinematic viscosity.
ρ_o	The standard density.	$V_x(y)$	The net axial velocity.
$\eta(x, t)$	The vertical wall displacement.	$G(y)$	The mean velocity perturbation function.
a	The wave amplitude.	B_o	The magnetic flux at the origin.
λ	The wavelength.	σ	Electrical conductivity.
c	The wave speed.	H_a	Hartmann number.
L	Compliant wall differential operator.	\vec{F}	Electromagnetic force.
T	Longitudinal tension per unit width	$\langle Q \rangle$	The net flow rate.
m	Mass per unit area.
