

**COMBINED POISEUILLE- COUETTE STATIONARY FLOW  
FOR A FLUID OF GRADE TWO WITHIN THE ANNULAR  
REGION BETWEEN TWO ECCENTRIC TUBES**

**A. ABU-EL HASSAN**

*Physics Department, Faculty of Science (Benha), Egypt*

**ABSTRACT**

*The flow of a viscoelastic fluid of grade two which performs a combined Poiseuille -Couette flow in the annular region between two eccentric tubes is investigated . A concised review of the first -order solution (3,7) is given in order to form a suitable basis for the present calculation.*

*The results of the present work suggests a major modification of the eccentric-cylinder rheometer (1) which is based on the pure Couette flow. From the practical point of view , a rheometer based on the combined Poiseuille-Couette flow can be realized and is expected to give more information than the present one.*

*Key words : Viscoelastic fluid, Eccentric tubes ,Poiseuille - Couette flow , Secondary flow.*

**1. INTRODUCTION**

In an extensive theoretical study of the steady state motion of a fluid of grade two in the annular region between two eccentric tubes, the velocity field due to superposition of rectilinear shearing, Poiseuille and Couette flow is investigated (3,7). The calculations are carried out

*A. Abu-El Hassan*

within the limit of the retarded motion expansion (4). Up to the first-order (viscous or Navier-Stokes fluid), the three motions create three independent contributions; namely  $\mathbb{W}_{1s}(\zeta, \eta)$  for simple shearing,  $\mathbb{W}_{1p}(\zeta, \eta)$  for Poiseuille flow and  $\underline{u}_1(\xi, \eta)$  for Couette flow. Provided each of the afore-mentioned three motions is considered separately, the velocity field for a fluid of grade two coincides with that of the Navier-Stokes fluid. However, if any of the two axial motions is superimposed on the Couette flow, a second-order contribution  $\mathbb{W}_2(\zeta, \eta)$  takes place. This second-order term results as an interaction between axial and rotational flow. The second-order term  $\mathbb{W}_2(\zeta, \eta)$  is already calculated (3,7) for the combination of simple shearing and Couette flow; i.e. for the so called helical flow.

In the work (3,7), the authors suggested the application of this boundary value problem for the construction of a rheometer which allows the determination of some of the second-order (elastic) constants besides the first-order (Newtonian) viscosity.

This suggestion is realized partially in a very important and fundamental contribution to Rheometry (1,2). In this work a rheometer, termed a new eccentric cylinder rheometer, is constructed on the basis of the pure Couette flow. The authors corrected the stream function for the first order Couette flow given in (3,7). They showed that the rheometer is capable of determining the shear viscosity  $\mu$  and the second-order elastic constant  $\alpha_1$  in a convenient way and only by one and the same set up. Due to the impossibility of realizing the combination of simple shearing and Couette flow, a further development of the eccentric cylinder rheometer is not possible. However, the combined Poiseuille-Couette flow is much easier to be realized. Hence, the aim of the present work is to determine the

second order velocity field  $W_2(\zeta, \eta)$  hen Poiseuille flow is superimposed on Couette flow.

## 2. Formulation Of The Problem

The fluid of grade two is assumed to perform isochoric and steady motion in the annular region between two eccentric cylinders of radii  $R_1, R_2$  ( $R_1 < R_2$ ) and of infinite lengths. The two axis of the cylinders stand parallel to each other and to the  $X_3$  - axis. The geometry of the problem suggests the use of cylindrical bipolar coordinates  $(\zeta, \eta, z)$ . This system of coordinates is generated from the rectangular system of coordinates  $(X_1, X_2, X_3)$  by the conformal transformation (5).

$$W = 2th^{-1}z/c \quad Z = X_3 \quad (1)$$

where

$W = \zeta + i\eta$  and  $Z = x_1 + ix_2$ . Eq (1) is equivalent to the real transformation

$$\begin{aligned} x_1 &= h \operatorname{sh} \zeta & ; & \quad \zeta = \operatorname{tanh}^{-1} \left[ \frac{2cx_1}{c^2 + x_1^2 + x_2^2} \right] \\ x_2 &= h \sin \eta & ; & \quad \eta = \tan^{-1} \left[ \frac{2cx_2}{c^2 - x_1^2 - x_2^2} \right] \\ x_3 &= z & ; & \quad z = x_3 \end{aligned} \quad (2)$$

where  $h = c/(\operatorname{ch} \zeta + \cos \eta)$  is the scale factor for the bipolar coordinates. The cross-section of the flow region is shown in Fig (1) where  $\zeta_1$  and  $\zeta_2$  represent the cross-sections of the inner and outer cylinders; respectively.

**A. Abu-El Hassan**

The first-order velocity field calculated in (3,7) is given by the expression ,

$$\underline{V} = \hat{Z} [ W_{1s} + W_{1p} ] + \underline{u}_1 (\zeta, \eta), \tag{3}$$

where the three contributions  $W_{1s}$ ,  $W_{1p}$  and  $\underline{u}_1$  are explained as follows

(i) The simple shearing created by the axial sliding of the inner tube with constant velocity  $W_0 \hat{z}$  induces a velocity field given by

$$W_{1s} \hat{z} = W_0 \frac{\zeta - \zeta_2}{\zeta_1 - \zeta_2} \hat{z} + o(W_0^2) \tag{4}$$

(ii) The Poiseuille flow due to the constant pressure gradient "a" in the axial direction creates the velocity field

$$\begin{aligned} W_{1p} \hat{z} = \frac{ac^2}{2\mu} \hat{z} & \left\{ \frac{\zeta - \zeta_2}{\zeta_1 - \zeta_2} \coth \zeta_1 + \frac{\zeta_1 - \zeta}{\zeta_1 - \zeta_2} \coth \zeta_2 - \frac{\text{ch} \zeta}{\text{ch} \zeta + \cos \zeta} + \right. \\ & + \sum_{n=1}^{\infty} \frac{2(-1)^n \cos n\eta}{\text{sh} n(\zeta_1 - \zeta_2)} \left[ \coth \zeta_1 e^{-n\zeta_1} \text{sh} n(\zeta - \zeta_2) \right. \\ & \left. \left. + \coth \zeta_2 e^{-n\zeta_2} \text{sh} n(\zeta_1 - \zeta) \right] \right\} + o(\alpha^2) \tag{5*} \end{aligned}$$

(iii) The Couette flow due to the rotation of the inner tube about its own axis with constant angular velocity  $\Omega$  is given by

$$\underline{u}_1 = -\hat{z} \wedge \nabla \psi_1 = h^{-1} [ \hat{\zeta} \psi_{1,\eta} - \hat{\eta} \psi_{1,\zeta} ], \tag{6a}$$

\* The final solution  $W_{1p}$  given in (3.7) includes a mistake which is corrected here

**A. ABU-EL HASSAN**

Where

$$\begin{aligned} \Psi_1 = & Qh(\zeta, \eta) \{ \wedge [ (\zeta_1 - \zeta) \text{sh} \delta \text{sh}(\zeta_1 - \zeta) \\ & - \delta (\zeta - \zeta_2) \text{sh}(\zeta_1 - \zeta) ] + \frac{\text{ch} \zeta_1}{\delta \text{sh} \delta} (\zeta - \zeta_2) \text{sh}(\zeta - \zeta_2) \\ & + \frac{\cos \eta}{\delta \text{ch} \delta - \text{sh} \delta} [ (\zeta - \zeta_2) \text{ch} \delta - \text{ch}(\zeta_1 - \zeta) \text{sh}(\zeta - \zeta_2) ] \} \\ & + O(a^2) \end{aligned} \quad (6b)$$

where

$$\wedge = [ \text{sh}^2 \delta - \delta^2 ]^{-1} \left[ \frac{\text{sh} \delta \text{ch} \zeta_1 + \delta \text{ch} \zeta_2}{\delta \text{sh} \delta} + \frac{c\Omega}{Q \text{sh} \zeta_1} \right]$$

The rate of flow,  $cQ$ , about the inner tube calculated per unit length is related to the angular velocity  $\Omega$  by the relation

$$Q = \frac{c\Omega}{\text{sh} \zeta_1} \left[ \frac{(\delta \text{ch} \delta - \text{sh} \delta) (\delta \text{sh} \zeta_1 - \text{sh} \delta \text{sh} \zeta_2)}{\text{sh} \delta [ \text{ch} \sigma (\delta \text{ch} \delta - \text{sh} \delta) + \text{sh} \delta \text{ch} \delta - \delta ]} \right] \quad (6-c)$$

where  $\delta = \zeta_1 - \zeta_2$  and  $\sigma = \zeta_1 + \zeta_2$ .

The equation determining the second - order solution is the Poisson equation given by

$$\nabla^2 w_2 + \frac{\alpha_1 + \alpha_2}{\mu} \nabla \cdot [ \nabla w_{1p} ( \nabla \underline{u}_1 + ( \nabla \underline{u}_1 )^T ) ] = 0,$$

$$W_2 = \begin{Bmatrix} 0 \\ 0 \end{Bmatrix} \text{ at } \zeta = \begin{Bmatrix} \zeta_1 \\ \zeta_2 \end{Bmatrix}, \quad (7)$$

where  $\underline{u}_1$  is the rotational flow defined by Eqs. ( 6a - 6c ) and  $W_1$  is, in the present case, the Poiseuille flow defined by Eq (5).

The constants  $\mu$ ,  $\alpha_1$  and  $\alpha_2$  are the viscosity and the second - order material coefficients according to the constitutive equation

*A. Abu-El Hassan*

$$\underline{\underline{T}} = -P\underline{\underline{I}} + \mu\underline{\underline{A}}_1 + \alpha_1\underline{\underline{A}}_2 + \alpha_2\underline{\underline{A}}_1^2; [3], \quad (8a)$$

where

$$\underline{\underline{A}}_1 = \nabla \underline{u}_1 + (\nabla \underline{u}_1)^T. \quad (8b)$$

and

$$\underline{\underline{A}}_2 = \frac{D\underline{\underline{A}}_1}{Dt} + \nabla \underline{u}_1 \cdot \underline{\underline{A}}_1 + \underline{\underline{A}}_1 \cdot (\nabla \underline{u}_1)^T \quad (8c)$$

In Eq. (8a)  $\underline{\underline{T}}$  is the stress tensor,  $P$  is the hydrostatic pressure and  $\underline{\underline{I}}$  is the unit tensor. It is obvious that  $\underline{\underline{A}}_2$  and  $\underline{\underline{A}}_1^2$  are second-order terms in the velocity field.

Eq. (7) implies that  $W_2$  is, as mentioned before different from zero only, if both  $W_1$  and  $\underline{u}_1$  are different from zero.

### 3. Solution of the problem

The solution given in (3,7) for the case of helical flow was performed in terms of the proper Green function, the simplicity of the density function left the integration over the Green function within tractable limits. However, the density function  $\nabla \cdot \left\{ \nabla W_1 \cdot [\nabla \underline{u}_1 + (\nabla \underline{u}_1)^T] \right\}$  with  $W_1$  given by Eq. (5) is so complicated that the integration process is associated with serious difficulties. Fortunately, a close investigation of the density function shows that a solution for Eq. (7) can be obtained directly.

Consider,

$$\begin{aligned}
 & \nabla \cdot \{ \nabla W_1 \cdot [ \nabla \underline{u}_1 + (\nabla \underline{u}_1)^T ] \} \\
 &= \nabla \cdot [ \nabla W_1 \cdot \nabla \underline{u}_1 + \nabla \underline{u}_1 \cdot \nabla W_1 ] \\
 &= \nabla \cdot [ \nabla (\underline{u}_1 \cdot \nabla W_1) - \underline{u}_1 \cdot \nabla \nabla W_1 + \nabla W_1 \cdot \nabla \underline{u}_1 ] \\
 &= \nabla^2 [ \underline{u}_1 \cdot \nabla W_1 ] - \nabla \underline{u}_1 : \nabla \nabla W_1 - \underline{u}_1 \cdot \nabla (\nabla^2 W_1) \\
 &+ \nabla \nabla W_1 : \nabla \underline{u}_1 + \nabla W_1 \cdot \nabla (\nabla \cdot \underline{u}_1) \\
 &= \nabla^2 (\underline{u}_1 \cdot \nabla W_1). \tag{9}
 \end{aligned}$$

Since  $\nabla \cdot \underline{u}_1 = 0$  by the equation of continuity and

$$\underline{u}_1 \cdot \nabla (\nabla^2 W_1) = \underline{u}_1 \cdot \nabla \left( -\frac{\rho}{\mu} \right) = 0.$$

Substituting from Eq (9) into Eq. (7) we obtain the following equation

$$\nabla^2 \left[ W_2 + \frac{\alpha_1 + \alpha_2}{\mu} \underline{u}_1 \cdot \nabla W_1 \right] = 0, \tag{10}$$

which has the solution .

$$W_2 = -\frac{\alpha_1 + \alpha_2}{\mu} \underline{u}_1 \cdot \nabla W_1 + W_2^{(h)},$$

where  $W_2^{(h)}$  is the solution of the Laplace equation  $\nabla^2 W_2 = 0$ .

Since  $\underline{u}_1 \cdot \nabla W_1$  satisfies the boundary conditions, then  $W_2^{(h)}$  is equal to zero. Hence ,

$$\begin{aligned}
 W_2 &= -\frac{\alpha_1 + \alpha_2}{\mu} \underline{u}_1 \cdot \nabla W_1 \\
 &= -\frac{\alpha_1 + \alpha_2}{\mu} h^{-1} (u_{1,\zeta} W_{1,\zeta} + u_{1,\eta} W_{1,\eta}). \tag{11}
 \end{aligned}$$

$u_{1,\zeta}$  and  $u_{1,\eta}$  are to be calculated from  $\psi_1$ , Eq (6b), and  $W_{1,\zeta}$  and  $W_{1,\eta}$  are to be calculated from  $W_{1p}$ ; Eq. (5).

**A. Abu-El Hassan**

Therefore,

$$u_{1,\zeta} = \frac{Qh}{C} \sin \eta \left\{ \left[ (\zeta_1 - \zeta) \operatorname{sh} \delta \operatorname{sh}(\zeta - \zeta_2) - \delta(\zeta - \zeta_2) \operatorname{sh}(\zeta_1 - \zeta) \right] - \frac{\operatorname{ch} \zeta_1}{\delta \operatorname{sh} \delta} (\zeta - \zeta_2) \operatorname{sh}(\zeta - \zeta_2) - \frac{\operatorname{ch} \zeta}{\delta \operatorname{ch} \delta - \operatorname{sh} \delta} \left[ (\zeta - \zeta_2) \operatorname{ch} \delta - \operatorname{ch}(\zeta_1 - \zeta) \operatorname{sh}(\zeta - \zeta_2) \right] \right\} \quad (12a)$$

$$u_{1,\eta} = \frac{Qh}{C} \left\{ \frac{h^{-1}}{C} \left[ \operatorname{sh} \delta \operatorname{sh}(\zeta - \zeta_2) + \delta \operatorname{sh}(\zeta_1 - \zeta) \right] - \frac{\operatorname{ch} \zeta_1}{\delta \operatorname{sh} \delta} \operatorname{sh}(\zeta - \zeta_2) + \frac{\operatorname{ch}(\sigma - 2\zeta) - \operatorname{ch} \delta}{\delta \operatorname{ch} \delta - \operatorname{sh} \delta} \cos \eta \right\} - (\operatorname{ch} \zeta_2 + \operatorname{ch}(\zeta - \zeta_2) \cos \eta) \left\{ (\zeta_1 - \zeta) \operatorname{sh} \delta + \frac{\zeta - \zeta_2}{\delta \operatorname{sh} \delta} \operatorname{ch} \zeta_1 \right\} - (\operatorname{ch} \zeta_1 + \operatorname{ch}(\zeta_1 - \zeta) \cos \eta) \delta \operatorname{sh}(\zeta - \zeta_2) + \frac{\operatorname{sh} \zeta \cos \eta}{\delta \operatorname{ch} \delta - \operatorname{sh} \delta} \left[ (\zeta - \zeta_2) \operatorname{ch} \delta - \operatorname{ch}(\zeta_1 - \zeta) \operatorname{sh}(\zeta - \zeta_2) \right] \right\}. \quad (12b)$$

$$W_{1,\zeta} = \frac{-a c^2 h^{-1}}{2\mu} \left[ -\frac{\operatorname{cth} \zeta_2 - \operatorname{cth} \zeta_1}{\delta} + \frac{\operatorname{sh} \zeta \cos \eta}{(\operatorname{ch} \zeta + \cos \eta)^2} + \sum_{n=1}^{\infty} \frac{2n(-1)^n \sin \eta}{\operatorname{sh} n \delta} \right] \left[ \operatorname{cth} \zeta_1 e^{-n\zeta_1} \operatorname{chn}(\zeta - \zeta_2) - \operatorname{cth} \zeta_2 e^{-n\zeta_2} \operatorname{chn}(\zeta_1 - \zeta) \right]. \quad (12c)$$

$$W_{1,\eta} = \frac{-a c^2 h^{-1}}{2\mu} \left[ \frac{\operatorname{ch} \zeta \sin \eta}{(\operatorname{ch} \zeta + \cos \eta)^2} + \sum_{n=1}^{\infty} \frac{2n(-1)^n \sin \eta}{\operatorname{sh} n \delta} \right] \left[ \operatorname{cth} \zeta_1 e^{-n\zeta_1} \operatorname{shn}(\zeta - \zeta_2) - \operatorname{cth} \zeta_2 e^{-n\zeta_2} \operatorname{shn}(\zeta_1 - \zeta) \right]. \quad (12d)$$

Substituting Eqs (12a) - (12d) into Eq (11) we get the proper expression for  $W_2(\zeta, \eta)$ .

This expression is quite complicated. The construction of rheometers is frequently done for narrow annular width. Thus the previous expressions will be approximated for the case  $\delta = \zeta_1 - \zeta_2 \ll \zeta_2$ . Moreover, the change of variables

**A. ABU-EL HASSAN**

$$y = \frac{\zeta - \zeta_2}{\delta},$$

shows to be useful, because it reduces the range

$$\zeta_2 \leq \zeta \leq \zeta_1 \quad \text{to} \quad 0 \leq y \leq 1.$$

Substituting the last transformation into Eq (12a) we get

$$u_{1\zeta} = \frac{Qh \sin \eta}{c} \{ \delta^\Delta [(1-y) \text{sh } \delta \text{ sh } \delta y - \delta y \text{ sh } \delta (1-y)] \\ + \frac{\text{ch } \zeta_1}{\text{sh } \delta} \text{sh } \delta y - \frac{\text{ch } \zeta}{\delta \text{ ch } \delta - \text{sh } \delta} [\delta y \text{ ch } \delta - \text{ch } \delta (1-y) \text{sh } \delta y] \}.$$

Expanding the hyperbolic functions in terms of power series, and neglecting terms of  $O(\delta^2)$  relative to one, then

$$u_{1\zeta} = \frac{Q \delta h(y, \eta) y^2 (1-y)}{c} \sin \eta \left[ \frac{c\Omega}{Q \text{sh } \zeta_1} + 2(1-y) \text{sh } \zeta_2 \right]$$

$$\text{With } u_{1\zeta} = \begin{Bmatrix} 0 \\ 0 \end{Bmatrix} \quad \text{at } y = \begin{Bmatrix} 1 \\ 0 \end{Bmatrix}, \quad (14a)$$

and Eq. (12b) reduces to

$$u_{1\eta} = \frac{yQh(y, \eta)}{c} \{ (\text{ch } \zeta + \cos \eta) \left[ \frac{\delta^\Delta}{6} (3y-1) - \frac{\text{ch } \zeta_1}{\delta} \right. \\ \left. - \frac{6(y-1)}{\delta} \cos \eta \right] - (\text{ch } \zeta_2 + \text{ch } \delta y \cos \eta) \frac{\text{ch } \zeta_1}{\text{sh } \delta} + y(3-2y) \text{sh } \zeta \cos \eta \},$$

$$\text{with } u_{1\eta} = \begin{Bmatrix} \Omega / \text{sh } \zeta_1 \\ 0 \end{Bmatrix} \quad \text{at } y = \begin{Bmatrix} 1 \\ 0 \end{Bmatrix}, \quad (14b)$$

*A. Abu-El Hassan*

In the same manner where  $\coth \zeta$  is expanded according to the relation,

$$\coth \zeta = \coth(\zeta_2 + \delta y) = \coth \zeta_2 - \frac{\delta y}{\operatorname{sh}^2 \zeta_2},$$

which on substitution into Eq. (5) leads to

$$W_1 = \frac{a\delta c^2}{2\mu \operatorname{sh}^2 \zeta_2} \sum_{n=1}^{\alpha} \frac{2(-1)^n e^{-n\zeta_2}}{\operatorname{sh} n\delta} [y e^{-n\delta y} \operatorname{sh} n\delta - e^{-n\delta} \operatorname{sh} n\delta y] \cos n\eta$$

$$\text{with } w_1 = \begin{Bmatrix} 0 \\ 0 \end{Bmatrix} \text{ at } y = \begin{Bmatrix} 1 \\ 0 \end{Bmatrix}. \quad (15a)$$

Therefore

$$W_{1,\zeta} = \frac{ac^2}{\mu \operatorname{sh}^2 \zeta_2} \sum_{n=1}^{\infty} \frac{(-1)^n e^{-n\zeta_2}}{\operatorname{sh} n\delta} [(1 - n\delta y) e^{-n\delta y} \operatorname{sh} n\delta - n\delta e^{-n\delta} \operatorname{ch} n\delta y] \cos n\eta.$$

$$\text{with } W_{1,\zeta} \neq 0 \text{ at } y = \begin{Bmatrix} 1 \\ 0 \end{Bmatrix}, \quad (15b)$$

and

$$W_{1,\eta} = \frac{\alpha \delta^2 c}{\mu \operatorname{sh}^2 \zeta_2} \sum_{n=1}^{\alpha} n(-1)^{n+1} [y e^{-n\delta y} \operatorname{sh} n\delta - e^{-n\delta} \operatorname{sh} n\delta y] \sin n\eta$$

(15c)

$$\text{with } W_{1,\eta} = \begin{Bmatrix} 0 \\ 0 \end{Bmatrix} \text{ at } y = \begin{Bmatrix} 0 \\ 0 \end{Bmatrix}.$$

Substituting by Eqs.(14a),(14b),(15b) and (15c) into Eq. (11), the approximated form of  $W_2$  is given by

$$\begin{aligned}
 W_2 = & -\frac{\alpha(\alpha_1 + \alpha_2) Q c y}{\mu \operatorname{sh}^2 \zeta_2} \sum_{n=1}^{\infty} (-1)^n e^{-n \zeta_2} \left\{ y(1-y) \left( \frac{\operatorname{ch} \zeta_1 + \operatorname{ch} \zeta_2}{Q \operatorname{sh} \zeta_1} \right) \right. \\
 & \left. \operatorname{ch} \zeta_1 - (3-2y) \operatorname{ch} \zeta \right\} \left[ e^{-n \delta y} (1 - n \delta y) - n \delta e^{-n \delta} \operatorname{coth} n \delta y \right] \\
 & y \sin \eta \cos n \eta - \left( \operatorname{ch} \zeta + \cos \eta \right) \left[ \frac{3y-1}{2} \left( \frac{\operatorname{ch} \zeta_1}{\delta} + \frac{\operatorname{ch} \zeta_2}{\operatorname{sh} \delta} \right) \right. \\
 & \left. + \frac{c \Omega}{Q \operatorname{sh} \zeta_1} \right] - \frac{\operatorname{ch} \zeta_1}{\delta} - \frac{6(y-1)}{\delta} \cos \eta \left. \right] - (\operatorname{ch} \zeta_2 + \operatorname{ch} \delta y \cos \eta) \frac{\operatorname{ch} \zeta_1}{\operatorname{sh} \delta} \\
 & + y(3-2y) \operatorname{sh} \zeta \cos \eta \left. \right) \left( y e^{-n \delta y} - e^{-n \delta} \frac{\operatorname{sh} n \delta y}{\operatorname{sh} n \delta} \right) n \delta \sin n \eta \left. \right\} \\
 \text{with } W_2 = & \begin{Bmatrix} 0 \\ 0 \end{Bmatrix} \quad \text{at } y = \begin{Bmatrix} 1 \\ 0 \end{Bmatrix}. \quad (16)
 \end{aligned}$$

### DISCUSSION

Figure (2) shows the dependence of the normalized second-order velocity field,

$$W_2^* = \frac{-\mu W_2}{\alpha(\alpha_1 + \alpha_2) Q c} \cdot 10^4$$

as function of the coordinate  $y$ , whereas the coordinate  $\eta$  serves as a parameter. The constants in Eq (16) are set  $\zeta_1 = 1.1$ ,  $\zeta_2 = 1$ ; i.e.  $\delta = 0.1$ . Figure (2) reveals that  $W_2^*$  possesses complicated behavior which will be discussed in the following points:

*A. Abu-El Hassan*

(i) Eq. (16) shows that

$$W_2^*(y, 0) = W_2^*(y, \pi) = 0 \text{ such that } W_2^* = 0$$

on the line of centers of the two cylinders.

(ii) The analysis of the curves start at  $y=0$ ; i. e., at the wall of the rotating inner cylinder. The curve representing  $W_2^*(y, \pi/4)$  describes the second - order velocity on a line which crosses the annular width in the narrow region. On this curve  $W_2^*$  increases in magnitude with negative values up to a minimum at  $y \approx 0.15$  then goes to zero at  $y \approx 0.43$ . Thus, in the interval  $0 \leq y \leq 0.43$ ,  $W_2^*(y, \pi/4)$  opposes the primary flow and slows down the velocity of the fluid. On the other hand, in the region  $0.43 \leq y \leq 1$ ,  $W_2^*(y, \pi/4)$  is positive with a maximum at  $y \approx 0.65$ . In this interval the resultant axial velocity is greater than the primary flow alone.

(iii) The curve  $W_2^*(y, \pi/2)$  which still lies in the narrower region of the annular width shows the same behavior at the previous curve. However,  $|W_2^*(y, \pi/2)| < |W_2^*(y, \pi/4)|$  on the whole interval  $0 \leq y \leq 1$  except in the small interval  $0.375 < y < 0.45$  as  $W_2^* \rightarrow 0$  and in the interval  $0.8 \leq y \leq 1$ .

(iv) The curve  $W_2^*(y, 3\pi/4)$ , which lies in the wider region of the annular width, shows different behavior. Within the interval  $0 \leq y \leq 0.24$   $W_2^*(y, 3\pi/4)$  is positive with maximum at  $y \approx 0.1$ , such that the resultant axial velocity is greater than the primary velocity  $W_1^*$ . In the middle region  $0.24 \leq y \leq 0.85$ ,  $W_2^*(y, 3\pi/4)$  is negative with minimum at  $y \approx 0.53$ . The motion of the fluid in this region is slower than the primary motion. Finally, in the interval  $0.85 \leq y \leq 1$ ,  $W_2^*(y, 3\pi/4)$  is positive with maximum at  $y \approx 0.92$ . This behavior shows that the velocity distribution tends to be flatter than the

## *A. ABU-El HASSAN*

distribution of the primary axial velocity.

(v) Close investigation of the construction of the eccentric cylinder rheometer (1,6) shows that its modification to include the Poiseuille axial flow is quite possible. However, to get the practical formulas to be applied in this case a careful calculation of the surface tractions, forces and torques at the wall of the outer cylinder is necessary. These calculations will be the subject of a further work.

المحصور بين اسطوانتين غير متحدثى المحور**

د. عبد الجليل أبو الحسن

قسم الفيزياء- كلية العلوم- بنها، فرع جامعة الزقازيق- مصر

فى هذا البحث تم تعيين مجال السرعة من الدرجة الثانية  $-W_2$ -  
الناشئ من تدفق سوائل الدرجة الثانية تحت تأثير حركتين (سريان بوازي +  
سريان كويبت) فى الفراغ الحلقى بين إسطوانتين لامركزييتين، ومن الجدير  
ذكره أن مسألة الشروط الحدية لاسطوانتين لامركزييتين قد تم دراستها فى  
بحث سابق وقد بنى على أساسها جهاز ريومترى يعتمد على الحركة  
الدورانية فقط. هذا وقد أجرى هذا البحث بغرض تطوير هذا الجهاز السابق  
وتوسيع مجال تطبيقه.
